## Tidal Reduction Tables

### Explanation

The following tables aim to provide a simple method of determining the approximate height of tide at times not predicted in the main tables.

To use the table:

- (1) Find out whether the required tide is on the ebb or flood, and also the nearest high water.
- (2) Take out the 'Range of Tide' from the 'ebb' or 'flood' column of the tables for the nearest high water.
- (3) Enter the reduction table with the time before or after high water on top and the 'Range' at the side and take out the height in feet or metres above low water from this table.
- (4) To this result add the height of nearest low water.
- (5) The final result will be the tidal height referred to port low water datum for the given time.

**CAUTION:** - The predictions by these tables must be taken as approximate on account of variations in level due to meteorological conditions. It should be noted that when the local barometer pressure is over 1016mb (30.00"), and particularly if this is accompanied by N to NE winds of force 5 or upwards, tidal levels may be considerably lowered. Conversely; When it is below 1016mb those heights may be exceeded.

The changes in sea level referred to are usually slow; thus in the Haven at the beginning of a period of high barometer and out blowing winds, sea level may drop, and supposing the barometer and wind remain constant, continue to drop for several days until a height, depending on the height of the barometer and force of wind, is reached. Sea level will probably then remain constant until the barometer begins to drop and the wind to decrease, when a gradual rise to normal begins, but may not be completed until some time after weather conditions have become normal.

Height in feet to be added to low Water to obtain height at intervening intervals (in hours)
